

- 1 A circular satellite dish, with centre O , is held in place by a straight support strut AT . The strut touches the edge of the dish only at point T , so AT is a tangent to the circle at T . OA is a support beam running from the centre O to the base of the mount at A , and OT is a radius of the dish.
- Given that $OA = 4.6$ m and $OT = 1.8$ m, find the angle $x = \angle OAT$ between the beam OA and the strut AT .

$$x = \dots\dots\dots^\circ$$
